California’s Most Vulnerable Parents
Infant Birth Weight and Maltreatment of Adolescent Mothers

INTRODUCTION

In 2010, 1 of every 30 infants in the United States was born to a teenage mother. Pregnancy during adolescence is associated with many later adversities for both mother and child, including low birth weight. Although the mechanisms remain unclear, low birth weight among infants born to teenage mothers may be attributable to adolescent health behaviors, access to health information and care, or unmeasured maternal selection effects. For example, among women of all ages, smoking is predictive of low birth weight and preterm delivery. Timing and duration of prenatal care is also associated with birth outcomes. Lack of prenatal care is associated with increases in preterm births (2.8 times higher for Black and White women), as is delayed receipt of prenatal care. Almost 25% of teen mothers do not receive prenatal care until their third trimester. Exposure to stress and adversity may have health consequences for pregnant women and their unborn children. Pregnant teens with a history of maltreatment may have a particularly acute vulnerability to poor birth outcomes. The traumatic stress associated with maltreatment not only increases the likelihood of substance use and engagement in other risk behaviors associated with infant birth weight, but may also instigate physiological changes that affect the course and outcome of pregnancy. Although a history of maltreatment may amplify pregnancy risk, few studies have attempted to quantify this possible relationship. Studies that have examined maternal maltreatment and infant birth outcomes have relied on self-reported maltreatment history, used small community samples, and did not focus specifically on preadolescent/adolescent maltreatment among teen mothers. This study builds upon prior research by exploring maternal maltreatment history as an independent predictor of low birth weight among infants born to teenage mothers. Specifically, it is the first to use population-based birth data linked to official child protection records to examine the effect of maternal maltreatment history on infant birth weight. Findings suggest that adolescents substantiated as victims of abuse or neglect were more likely to give birth to an infant of low birth weight than were sociodemographically similar adolescents who had not been maltreated. Although the increased risk was small and the mechanism unclear, these data suggest that maternal maltreatment may not only have consequences for the victim but may also contribute to intergenerational health disparities.
METHODS

DATA SOURCES

This study used vital birth records matched to administrative child protective services (CPS) records for the state of California. Maternal information for all singleton infants born between 2007 and 2009 to mothers aged 12–19 years was extracted from state vital statistics birth records. These records were linked to CPS data to identify teenage mothers whose maltreatment cases had been substantiated following a CPS investigation (California Welfare & Institutions Code § 300). Linkages were established using probabilistic linkage software in which record pairs were deemed a match or nonmatch based on a formal statistical model. Match cut-points were determined through an extensive examination of linked records and a subsequent clerical review of a specified range of uncertain matches falling above and below match thresholds.

Of the 153,743 singleton births to teenage mothers in California between January 1, 2007, and December 31, 2009, 7.1% (n = 10,866) were low birth weight (compared to 5.1% [p < .001] born to mothers older than 19). Among teenage mothers, 13.6% had been substantiated as a victim of maltreatment after age 10 and before giving birth. The proportion of low birth weight infants born to teenage mothers with a history of substantiated maltreatment was slightly higher than infants born to teens with no such history (14.7% vs. 13.5%, respectively, p < .001). Notable and statistically significant differences also emerged among other covariates. Younger maternal age and first birth were associated with an increased risk of low birth weight. Black and Asian/Pacific Islanders comprised a larger share of low birth weight infants than in the overall population of births to adolescent mothers. Infants born to mothers who smoked cigarettes during pregnancy were overrepresented among low birth weight infants; those born to teenage mothers receiving WIC benefits were underrepresented. Child gender and birth payment method were not associated with birth weight; subtle differences were observed by prenatal care.

Low birth weight was based on a gestational weight threshold of 2,500 grams. To isolate the potential effect of maternal maltreatment, eight confounders were included: (1) maternal age (12–16 years, 17–19 years); (2) birth order (first birth, subsequent birth); (3) maternal race/ethnicity (White, Black, Latina, Asian/Pacific Islander, Native American); (4) cigarette smoking during pregnancy (yes, no); (5) prenatal care initiation (first trimester, second trimester, third trimester/no care); (6) birth payment method (private insurance, public insurance); (7) Women, Infant, Children (WIC) utilization (yes, no); and (8) infant gender (female, male).

ANALYSIS

Descriptive statistics were computed and X² tests used to compare the distribution of maternal maltreatment and other sociodemographic characteristics stratified by infant birth weight (< 2,500 g vs. ≥ 2,500 g). To examine the effect of maternal maltreatment on infant birth weight, a log Poisson regression model with a robust variance estimation was specified. All analyses were conducted using StataSE software. Adjusted risk ratios (RRs) and corresponding 95% confidence intervals (CI) are reported.

RESULTS

Of the 153,743 singleton births to teenage mothers in California between January 1, 2007, and December 31, 2009, 7.1% (n = 10,866) were low birth weight (compared to 5.1% [p < .001] born to mothers older than 19). Among teenage mothers, 13.6% had been substantiated as a victim of maltreatment after age 10 and before giving birth. The proportion of low birth weight infants born to teenage mothers with a history of substantiated maltreatment was slightly higher than infants born to teens with no such history (14.7% vs. 13.5%, respectively, p < .001). Notable and statistically significant differences also emerged among other covariates. Younger maternal age and first birth were associated with an increased risk of low birth weight. Black and Asian/Pacific Islanders comprised a larger share of low birth weight infants than in the overall population of births to adolescent mothers. Infants born to mothers who smoked cigarettes during pregnancy were overrepresented among low birth weight infants; those born to teenage mothers receiving WIC benefits were underrepresented. Child gender and birth payment method were not associated with birth weight; subtle differences were observed by prenatal care.

The risk of low birth weight was 6% greater among infants born to adolescent mothers with a maltreatment history.

Children’s Data Network at the University of Southern California
Maternal maltreatment history was associated with a 10% increased risk of low birth weight (RR: 1.10; 95% CI: 1.04, 1.16). Maternal smoking, prenatal care, and other confounders modestly attenuated the association between maternal victimization and infant birth weight; yet after adjusting for these other factors, the risk of low birth weight was 6% greater among infants born to adolescent mothers with a maltreatment history (RR: 1.06; 95% CI: 1.01, 1.12). Bivariate associations observed for other covariates remained in the multivariable model, with the largest relative differences in birth weight associated with race/ethnicity, cigarette smoking, and receipt of WIC benefits.

Notes: Summed counts may not equal column totals due to missing values for some variables.

*p < .05; **p < .01; ***p < .001
CI = confidence interval; Adj. RR = adjusted risk ratio; Ref = reference group
The proportion of cases with missing values for a given variable ranged from 0% (child sex) to 3.2% (prenatal care).
DISCUSSION

SUMMARY

This was the first population-based study to validate the relationship between officially substantiated maternal maltreatment and low birth weight among infants born to teenage mothers. Previous research has demonstrated that child maltreatment is associated with negative outcomes during both childhood and adulthood. The results of this study suggest that the consequences of maltreatment may also be intergenerational. Although the magnitude of the effect was small relative to other established risk factors, maternal maltreatment history emerged as a significant and independent hazard for an already high-risk population of infants born to teenage mothers.

Previous research has demonstrated that child maltreatment is associated with negative outcomes during both childhood and adulthood.

LIMITATIONS

There are several limitations that must be noted. First, complete data for maltreatment after age 10 was available for examination; the number of mothers who experienced earlier maltreatment and how maltreatment prior to age 10 may have affected infant birth weight is unknown. Second, these data do not address the potential mechanisms by which maternal maltreatment affects birth weight. Third, other risk factors, such as prenatal drug or alcohol exposure, which may affect birth weight, were unavailable in the data. Last, the data included only a crude measure of maternal socioeconomic status (i.e., birth payment method) and therefore do not capture community-level poverty information. As such, it is unknown whether other measures of poverty would have moderated the observed relationship between maltreatment and birth weight.

These findings suggest maltreatment not only affects the health and emotional well-being of individual victims but also contributes to intergenerational health disparities.

CONCLUSIONS

The finding of a relationship between maltreatment history and infant birth weight aligns with research that similarly suggests that abuse and other adversities negatively affect health and well-being throughout the life course. The association between a history of maltreatment victimization and infant birth weight may reflect physiological changes or chronic maternal stress responses. Regardless of the mechanism and despite the modest effect relative to other risk factors, these findings are provocative in that they suggest maltreatment not only affects the health and emotional well-being of individual victims but also contributes to intergenerational health disparities. Future research is needed to explicate the relationship by which maltreatment affects maternal and child health, framing maltreatment as an adverse exposure that may influence the uterine environment.

RESEARCH FUNDING

The Conrad N. Hilton Foundation was created in 1944 by international business pioneer Conrad N. Hilton, who founded Hilton Hotels and left his fortune to help the world's disadvantaged and vulnerable people. The Foundation currently conducts strategic initiatives in six priority areas: providing safe water, ending chronic homelessness, preventing substance abuse, helping children affected by HIV and AIDS, supporting transition-age youth in foster care, and extending Conrad Hilton's support for the work of Catholic Sisters. Following selection by an independent international jury, the Foundation annually awards the $1.5 million Conrad N. Hilton Humanitarian Prize to a nonprofit organization doing extraordinary work to reduce human suffering. From its inception, the Foundation has awarded more than $1 billion in grants, distributing $83 million in the U.S. and around the world in 2012. The Foundation's current assets are in excess of $2.2 billion. For more information, please visit hiltonfoundation.org.
